Achilles tendon ruptures—a review for primary care

The Achilles tendon is the most commonly ruptured tendon and the incidence is increasing.1-3 Unfortunately, 20% to 25% of acute Achilles tendon ruptures are misdiagnosed initially.1-4 Diagnosis is based on history and physical examination. Use of MRI or ultrasound is not indicated unless there are equivocal physical exam findings.

Common mechanisms include pushing off with the weight-bearing foot while extending the knee; a sudden, unexpected dorsiflexion of the ankle; or violent ankle dorsiflexion of a plantarflexed foot. Patients often describe feeling as if they were kicked in the back of the ankle. Some will have minimal discomfort and may be weight-bearing. They may describe a “pop” at the time of injury. Fluoroquinolone or steroid use, diabetes, or chronic renal failure can increase the risk of rupture but make small contributions to overall incidence.5,6

The Thompson test is considered to be the most accurate—it is positive in 96% to 100% of acute ruptures.7-9 Other physical findings include a palpable tendon gap, tenderness, and possibly swelling/bruising depending on injury acuity. In the prone position with the patient’s feet off the examining table, the injured foot will hang in more dorsiflexion than the contra-lateral foot. The patient may be able to plantarflex and the Thompson test may result in some movement, but in both cases the injured side will be weaker and decreased compared with the uninjured side. This is due to other musculotendinous structures that pass the ankle posteriorly.

Treatment

Treatment of Achilles tendon ruptures is currently undergoing transition. Traditional treatment involves 12 weeks of immobilization. If treated surgically, the tendon is repaired and the foot immobilized in equinus. Immobilization could be splinting followed by casting at 2 weeks, or, more recently, a cast boot with heel wedges. If treated conservatively, the foot is immobilized in equinus.

Another approach is non-weight-bearing and the foot is incrementally brought up to a neutral position over approximately 6 weeks by recasting or removing the heel. The second 6 weeks have the foot immobilized at 90 degrees. Some surgeons may opt to allow protected weight-bearing at this point. If the injury is identified and treatment started within 14 days, the primary difference between the options is higher re-rupture rates with conservative management (meta-analyses found this to be approximately 3% vs 13%)10,11 vs the risks of surgery. Some surgeons believe surgical repair has better functional outcomes, but this has not been conclusively demonstrated.

A multicentre study in 2010 using an accelerated functional rehabilitation protocol changed the landscape.3 It found no clinically significant differences in outcome or re-rupture rates. This protocol involved limited immobilization with early motion. The original protocol (see Table)3 has since been slightly modified by various surgeons. This approach is currently used by a significant number of orthopaedic surgeons in BC. Other studies have validated the results of this approach.12-15 There may be an advantage of earlier return to work with surgical intervention.12 Surgical treatment remains the primary option for patients in whom treatment is begun more than 14 days after injury.

Acute Achilles ruptures are most common in male weekend warriors. Diagnosis is made with history and physical examination. Treatment can be conservative or surgical, with accelerated function rehabilitation offering conservative management the advantages of surgery without the risks. The conservative approach can be used only if treatment is initiated within 14 days of injury. A patient diagnosed with acute Achilles rupture should be immediately made non-weight-bearing, immobilized in equinus, and referred to the local orthopaedic surgeon on call. This will allow all treatment options to be available to the patient and treating surgeon.

### Table. Achilles tendon rupture rehabilitation protocol.

<table>
<thead>
<tr>
<th>Time frame</th>
<th>Activity</th>
</tr>
</thead>
<tbody>
<tr>
<td>0–2 weeks</td>
<td>Posterior slab/splint; non-weight-bearing with crutches: immediate post-op in surgical group, after injury in non-op group</td>
</tr>
</tbody>
</table>
| 2–4 weeks  | Aircast walking boot with 2-cm heel lift†  
Protected weight-bearing with crutches  
Active plantar flexion and dorsiflexion to neutral, inversion/eversion below neutral  
Modalities to control swelling  
Incision mobilization modalities‡  
Knee/hip exercises with no ankle involvement (e.g., leg lifts from sitting, prone, or side-lying position)  
Non-weight-bearing fitness/cardiovascular exercises (e.g., bicycling with one leg, deep-water running)  
Hydrotherapy (within motion and weight-bearing limitations) |
| 4–6 weeks  | Weight-bearing as tolerated†  
Continue 2–4 week protocol |
| 6–8 weeks  | Remove heel lift  
Weight-bearing as tolerated‡  
Dorsiflexion stretching, slowly  
Graduated resistance exercises (open and closed kinetic chain as well as functional activities)  
Proprioceptive and gait retraining  
Modalities including ice, heat, and ultrasound, as indicated  
Incision mobilization§  
Fitness/cardiovascular exercises to include weight-bearing as tolerated (e.g., bicycling, elliptical machine, walking or running on treadmill, stair climber)  
Hydrotherapy |
| 8–12 weeks | Wean off boot  
Return to crutches or cane as necessary and gradually wean off  
Continue to progress range of motion, strength, proprioception |
| >12 weeks  | Continue to progress range of motion, strength, proprioception  
Retrain strength, power, endurance  
Increase dynamic weight-bearing exercise, include plyometric training  
Sport-specific retraining |

* Patients were required to wear the boot while sleeping.
† Patients could remove the boot for bathing and dressing but were required to adhere to the weight-bearing restrictions according to the rehabilitation protocol.
‡ If, in the opinion of the physical therapist, scar mobilization was indicated (i.e., the scar was tight or not moving well), the physical therapist would attempt to mobilize using friction, ultrasound, or stretching (if appropriate). In many cases, heat was applied before beginning mobilization techniques.
